

修订说明（不进入正式文档，仅供对照）：子标题结构保持不变。每条事实被指定唯一的“归属小节”，其余小节如需提及，改为一句话+交叉引用，不再重述细节。改动幅度以最小编辑为原则——多数句子沿用原文，只做位置搬迁、去重和少量连接词调整。

6.5 Counterparty credit losses

The CCR RWA and CCR P&L Dry Runs were successfully completed as part of the EBA Advanced Data Collection (ADC) exercise to validate methodology, test end-to-end reporting processes, and obtain early data quality assurance feedback. Both workstreams demonstrated that the reporting process can reliably source, populate and reconcile data in line with EBA methodology, supported by appropriate governance and data quality controls (see 6.5.6 for Dry Run-specific findings and evidence).

6.5.1 Data Source

CCR RWA. The CCR RWA submission is sourced from the COREP regulatory reporting data extracted from the Axiom platform and provided by the RIS COREP & Pillar 3 team. The COREP dataset contains Exposure at Default (EAD), Risk Weighted Assets (RWA), asset class classifications, geography information and SME indicators, which are used to populate the EBA CSV_CR_REA template. COREP acts as the authoritative source for all reported CCR RWA figures.

CCR P&L. The CCR P&L process relies on several strategic systems that collectively provide exposure, counterparty and collateral data. The 3D Stress Engine provides stressed and unstressed counterparty exposure measures and serves as the primary source of stressed exposure data. CREDs and JUNO supply current exposure information and counterparty attributes used in the loss calculation process. STAR sources supporting information such as collateral agreements, thresholds and CSA terms. The 3D Database provides reference data including LEI mappings, product mappings, GNA mappings and Site IDs. Accounting CVA information is ultimately sourced from AXIS. Together, these systems form the core data infrastructure supporting the CCR P&L stress testing process.

In addition to these system feeds, the CCR P&L model requires several manually sourced inputs — stressed PD and LGD assumptions, accounting CVA adjustments, CRT hedge information and exposure adjustment files received from external teams — because certain inputs are generated outside the strategic model environment (treatment of these inputs is covered in 6.5.2; related architecture limitations are covered in 6.5.3).

6.5.2 Methodology and Assumptions

The CCR RWA and CCR P&L submissions are prepared in accordance with the EBA Stress Test methodology and reporting requirements applicable to the relevant exercise cycle.

CCR RWA. The process populates the EBA CSV_CR_REA template using regulatory COREP data. No manual overlays, expert judgement adjustments or stress-related data modifications are applied. EBA guidance does not require stressing CCR exposures or standardized risk weights for the Barclays Europe portfolio; therefore actual values are retained across the projection horizon, and adverse scenario projections are assumed equal to actual values. This treatment is supported by periodic impact assessments performed by the CCR Stress Testing team, which concluded that stressing standardized risk weights would have an immaterial impact on CCR RWA results, and is subject to governance and approval by senior Barclays Europe Risk and Stress Testing management. The process assumes the Barclays Europe (BBIE) portfolio is the relevant reporting scope and that COREP C.09.01 is the authoritative source for exposures and RWAs. Asset class mappings, geographical allocations and SME classifications (using the Risk Taker SME Indicator) are derived directly from COREP; Default Funds and Frees & Fails are excluded in accordance with the documented methodology. No material deviations from the documented methodology were identified for this workstream.

CCR P&L. The process follows the approved GMD2601 CCR P&L Stress Testing Model methodology and associated EBA requirements for the CSV_MR_CCR template, incorporating stressed counterparty exposures, stressed PDs and LGDs, counterparty default selection criteria, collateral treatment and loss calculations. Stressed exposure information from the 3D Stress Engine is combined with current exposure information from CREDS and JUNO; counterparties are selected for default based on exposure rankings and probability-of-default measures per EBA rules. Investigation thresholds of USD 100 million at Group level and USD 25 million at Barclays Europe level are used to identify counterparties requiring detailed review and potential adjustment (the mechanics of applying these thresholds are described in 6.5.4). Manually sourced inputs — PD/LGD overlays, CVA data and CRT hedges — are assumed to be fit for purpose, subject to confirmation from the relevant data providers. Where strategic system outputs do not fully reflect the required regulatory view, controlled manual adjustments are permitted: the most significant relates to exposure differences between 3D and CREDS/JUNO (root cause explained in 6.5.3), and additional overlays may be applied for missing risk factors where the estimated impact exceeds 5% of stressed exposure for defaulting counterparties. These are treated as approved model overlays — documented, reviewed, justified and governance-signed-off — rather than methodology breaches. The SOP does not quantify a fixed impact, as the size of these adjustments is exercise-specific.

6.5.3 Data Limitation and Mitigants

CCR RWA.

- *Limitations:* The process relies on receipt of COREP source files from the RIS COREP & Pillar 3 team through a manual email process rather than a fully automated strategic feed, creating dependency on timely delivery and completeness of supporting information (e.g. SME indicators, reconciliation artefacts). The EBA submission process is supported by an Excel-based EUDA, introducing manual population, mapping and reconciliation activity and associated operational risk. The total EBA submission combines CCR and WCR contributions, which can make investigation of reconciliation breaks more complex. The process also inherits any limitations, timing constraints or data quality issues present in the underlying COREP source reports; no dedicated DQMT framework exists for this workstream (see 6.5.5).
- *Mitigants:* The principal mitigation is a robust reconciliation and governance process — all populated template values are reconciled back to COREP source data, with Finance performing independent validation of EAD and RWA totals, plus additional checks at country, asset class and SME/non-SME level. Material breaks must be investigated, resolved or formally explained before submission. The EUDA is governed under the EUDA control framework, with version control, review requirements and evidence retention procedures. Residual risk from the manual nature of data handling and template population is mitigated through layered review and approval controls.

CCR P&L.

- *Limitations:* The process relies on multiple source systems and manual inputs, creating potential challenges around data consistency and completeness. The principal known limitation is architectural: certain exposure adjustments applied in CREDS are not propagated to the 3D database, while the stress-testing model sources stressed exposures from 3D. This creates an expected difference between the stressed exposure dataset (3D) and the current exposure dataset (CREDS/JUNO), which requires investigation and adjustment (the reconciliation mechanics for this are described in 6.5.4; it is not treated as a genuine data quality failure — see 6.5.5). The process also depends on manually supplied inputs (PD/LGD overlays, CVA data, CRT hedge information, static mapping tables), making data availability subject to external provider timelines. The methodology also acknowledges that some material risk factors may not be fully captured by upstream models, requiring ongoing monitoring and potential overlay.
- *Mitigants:* The primary mitigation for the 3D/CREDS exposure difference is reconciliation between the two datasets prior to model execution; material differences above the defined thresholds (per 6.5.2) are investigated and, where appropriate, exposure overwrite adjustments are applied to align the datasets. Manual inputs are subject to fit-for-purpose attestations from data providers, and significant adjustments require review

and governance approval. Model outputs are further subject to KPI monitoring, manual review and DQMT validation checks before final submission.

6.5.4 Data Reconciliation and Adjustments

CCR RWA. The submission is produced by sourcing CCR-specific COREP data (primarily the C.09.01 report: EAD, RWA, asset class, geography and SME indicators) from the Axiom platform. These elements are mapped into the EBA CSV_CR_REA template using the Excel-based EUDA, applying asset class mapping, country mapping and SME/non-SME classification logic, plus exclusion of Default Funds, Frees & Fails and certain cash clearing balances. Populated values are subsequently reconciled back to the underlying COREP reports, with additional validation performed against the CCR-specific C.07 and C.09 templates to confirm traceability to the regulatory reporting source. The SOP does not identify any recurring or known reconciliation breaks; where differences arise, Finance and the CCR Stress Testing team investigate whether they result from mapping, classification or population issues, and material breaks must be resolved or formally explained prior to submission approval. Because the EBA submission combines CCR and WCR contributions, reconciliation back to the CCR-specific COREP reports (rather than the combined EBA total) is treated as the primary control for investigating expected differences.

CCR P&L. The submission is derived through the GMD2601 model process: stressed exposure information is sourced from the 3D Stress Engine, current exposure data from CREDS/JUNO, and these are combined with stressed PDs, stressed LGDs, CVA adjustments and CRT hedge information to calculate final counterparty losses for population into the CSV_MR_CCR template, using mapping/reference tables linking counterparties, products, LEIs, countries and GNA structures. The comparison between 3D exposure data and CREDS/JUNO exposure data is performed before model execution, applying the USD 100mn (Group) / USD 25mn (Barclays Europe) thresholds defined in 6.5.2 to identify counterparties requiring detailed review; where variances exceed these thresholds, exposure adjustment overwrites are applied to align the datasets (the underlying architectural cause of these differences is described in 6.5.3). Additional overlays are applied for missing risk factors where the estimated impact exceeds 5% of stressed exposure, documented and subject to review, justification and governance sign-off. Prior to submission, model outputs are reconciled against source exposure datasets and validated through model controls and DQ checks (see 6.5.5) to ensure accuracy and completeness.

6.5.5 Summary of Data quality

CCR RWA. No dedicated DQMT process exists for this workstream, as the submission is based directly on COREP regulatory reporting data that has already undergone established Pillar 1 reporting controls and data quality checks. Data quality assurance is therefore achieved primarily through source-to-template reconciliation, Finance review and evidence

retention, focused on ensuring EAD and RWA values remain consistent with the CCR-specific COREP source reports. No unresolved FINREP or COREP reconciliation breaks are documented within the SOP; the expectation is full reconciliation, with any discrepancies investigated and resolved prior to submission, and Finance confirming material breaks have been adequately explained.

CCR P&L. This workstream includes a dedicated DQMT process, executed following population of the CSV_MR_CCR template, to verify completeness of mandatory reporting fields, validate data population and confirm compliance with EBA template requirements before submission — forming part of the final output validation and governance framework. Where DQ findings relate to missing mandatory fields requiring business justification rather than data correction, comments are added through the DQMT workflow to document the rationale and supporting evidence; these are not considered genuine data quality failures where the reported value remains EBA-compliant. Similarly, differences between 3D and CREDS exposure values (see 6.5.3) are not automatically treated as data quality issues, since they may reflect known architectural differences between the systems — they are investigated through the reconciliation and adjustment framework described in 6.5.4 rather than through the DQMT process.

Overall. The data quality framework is designed to ensure the EBA submission remains accurate, complete, traceable and appropriately governed. For CCR RWA, assurance is derived primarily from reliance on regulated COREP source data and independent Finance reconciliation. For CCR P&L, assurance is derived through model controls, source system reconciliations, provider attestations, threshold-based investigations, DQMT validations and formal sign-off procedures. Supporting evidence for both workstreams includes source data files, reconciliation workbooks, DQMT outputs, model monitoring reviews, provider confirmations and approval records maintained within the stress testing governance framework.

6.5.6 Comments on Results

CCR RWA Dry Run. Performed as part of the ADC exercise to support methodology validation, template familiarisation and early quality assurance activities. Results were derived from COREP data sourced from Axiom and populated into the CSV_CR_REA template through the established EUDA process. Reconciliation confirmed alignment between the populated template and the CCR-specific COREP C.09 and C.07 source reports, with **no material reconciliation breaks identified** during the Dry Run. Results are consistent with the approved EBA treatment (CCR RWA held unstressed, as exposures are subject to standardized risk weights and the majority of the portfolio is collateralized); no methodology deviations were identified. The Dry Run therefore demonstrated that the reporting process can produce complete, traceable CCR RWA outputs consistent with regulatory reporting source data. The primary item requiring future attention is the ongoing

transition to Basel 3.1-compliant risk weights: the current process relies on Basel 3 risk weights with PMA, meaning future restated FDC submissions will require updated Basel 3.1-aligned calculations once available. This does not affect the validity of the current Dry Run results but remains an area of ongoing remediation and development.

CCR P&L Dry Run. Performed using the strategic GMD2601 process and supporting data sourced from 3D, JUNO, CREDS and STAR. The exercise validated the strategic end-to-end reporting pipeline from model execution through MEF/MES and PASCAL to eventual population of the CSV_MR_CCR template; no methodology deviations were identified and the process operated as designed. The results demonstrate that the CCR P&L framework is capable of producing stressed counterparty loss outputs that are explainable, consistent and aligned with regulatory expectations, supported by structured controls, governance reviews and DQ validation activities. The principal data quality observations identified during the Dry Run related to DQMT validation flags for missing LEI information and alphanumeric validation rules; these were determined to be expected rather than genuine data quality issues, as the relevant legal entity identifier was unavailable for the group concerned and the remaining flags were triggered by expected naming conventions — with **no material impact on reported results**. No manual judgement was required in transferring model output into the EBA template, as the reporting process uses strategic automated pipelines, reducing operational risk and improving consistency between model outputs and regulatory submissions.
